### Amendments to the Specification:

Please amend paragraph [002] as follows:

[002] U.S. Patent Application Ser. No. <u>09/928,646</u> (Attorney Docket No. 044935.0000/1), entitled "PERSONALIZED DATA REPLICATION FOR WIRELESS DEVICES USING FILTERS," filed concurrently;

Please amend paragraph [003] as follows:

[003] U.S. Patent Application Ser. No. <u>09/928,650</u> (Attorney Docket No. 044935.0000/3), entitled "PROACTIVE DATA REPLICATION FOR WIRELESS DEVICES," filed concurrently; and

Please amend paragraph [004] as follows:

[004] U.S. Patent Application Ser. No. <u>09/928,964</u> (Attorney Docket No. 044935.0000/4), entitled "LOCATION BASED DATA REPLICATION FOR WIRELESS DEVICES," filed concurrently.

Please amend paragraph [006] as follows:

[006] Soon after computers were invented, people began connecting them together. Connections among multiple computers enabled scarce resources such as printers and memory devices to be shared. At first, connections between computers were established with wires, but, as technology advanced and a need

developed for more flexibility, wireless communication methods were created and deployed. Early wireless communication techniques involved periodically connecting a mobile device to a network access point via a cable or via infrared signals between the mobile computer device and the network access point. These techniques require either attaching wires to the mobile device or placing an infrared port on the mobile device within the limited range of a corresponding infrared port at the network access point. Basically, early wireless communication techniques enabled mobile devices to communicate with each other or other computers only within a limited physical range. The issue of limited range was addressed in the nineties when computing devices were designed to take advantage of new wireless communication networks, e.g., cellular telephone systems, that were beginning to appear around the United States and the world.

#### Please amend paragraph [007] as follows:

[007] By the late nineties, wireless networks spanned much of the world, allowing mobile computing devices to communicate from almost any location with each other and with remote computers hosting centralized data storage applications, or "data servers." For example, using these communication networks, [[a]] sales people, using wireless-modem equipped, laptop computers, can keep in touch with their company's centralized inventory and ordering systems. In addition, mobile devices such as personal digital assistants (PDAs) and sophisticated cellular telephones enable users to access the Internet, a world-wide collection of computers that collectively store vast resources of data. Some mobile devices are also able to access the public telephone network (PTN) and/or the Internet to communicate with each other.

## Please amend paragraph [010] as follows:

[010] A current solution to the problem of a limited area for input and output involves the use of handwriting recognition software. However, handwriting recognition software is typically quite large and thus the mobile device runs into the memory problem. Another solution is to provide a small keyboard. However, such keyboards are typically difficult to use. Another solution involves the use of screen icons, each of which represent represents a desired action, and a stylus, which is used to touch a particular icon on the display of the mobile device. When the stylus touches a particular icon, the action associated with the icon is initiated. Many PDAs have adopted this icon/stylus approach because it seems to offer the best balance between ease of input and the need to fit the applications that control input into a small memory.

#### Please amend paragraph [012] as follows:

[012] Of course, if one particular data source, such as a product database, stored on a remote computer, is shared among multiple users, issues relating to data consistency, or "data synchronization," arise. Data synchronization is the process ensuring the data in one database is identical to the corresponding data in another database so that any user of the data is aware of any changes made to the data by other users. For example, if a company has one baseball in stock and a first sales person sells that baseball, a second sales person needs to be aware that the company no longer has a baseball to sell. In order for the second sales person to know of the inventory update, at least two things must happen: (1) the first sales person must update the server to reflect the new number of baseballs; and (2) the

FEB-03-2005 20:58 FOXCONN 408 919 8353 P.06

data used by the second sales person, if local to the sale sales person's mobile device, must be updated to reflect the updated information on the server.

Please amend paragraph [0017] as follows:

[0017] Periodically during the off-line mode, the wireless computing device performs a synchronization; i.e., goes on-line in order to propagate to the remote data storage all data objects and actions saved since the last synchronization. A time interval between synchronization synchronizations is set either by a user of the wireless computing device, set by a system administrator on the remote server, or determined by external circumstances such as whether or not the wireless computing device is able to establish a connection with the remote server. In addition, the time interval can be determined by circumstances internal to the wireless computing device or remote server such as whether or not either the wireless computing device or the remote server [[have]] has made changes to the data objects that need to be synchronized. The time interval between synchronization synchronizations can be either regular or irregular and vary from less than a second to longer than a year. During synchronization, the server applies the data objects and corresponding actions to the server data storage either in the order the actions are received or based upon the corresponding time stamp timestamp. Update replication enables update operations on data objects to be performed locally when the mobile computing device is off-line. The update operations are saved and forwarded to the remote server during synchronization. The locally performed update operation is then executed on the remote server and results are transmitted back to the mobile wireless computing device.

>

#### DETAILED DESCRIPTION OF THE FIGURES INVENTION

Please amend paragraph [039] as follows:

- [039] A client library of the wireless application framework 301 provides the following functionality for [[a]] an associated, client application:
- (1) generating the contents (method names and parameters) of the remote procedure calls;
  - (2) forming an XML message;
  - (3) sending the XML message using the HTTP protocol to the server; and
  - (4) receiving and interpreting a corresponding response from the server.

A server library of the wireless application framework 301 provides the following functionality for an associated, server application:

- (1) receiving and interpreting a client request, specifically a request that has been generated, formed and sent by utilizing the client library, as described above;
- (2) locating an appropriate procedure, corresponding to the particular RPC requested in the client request;
  - (3) invoking the appropriate procedure; and
  - (4) sending the appropriate response back to the client.

The RPCs of the disclosed subject matter support the following data types in the wireless environment: integer (4 bytes)[[;]], boolean[[;]], string[[;]], date[[;]], double[[;]], base-64, arrays, structures and hash tables.

Please amend paragraph [040] as follows:

[040] The wireless data replicator 307 processes and manages data on the wireless devices. The wireless data replicator 307 enables a user to select the specific information that the user needs on the wireless device and, by replicating only the selected data, saves bandwidth on the transmission medium and memory resources on the wireless device. The wireless data replicator 307 uses the system database as a client data cache and provides each user of a wireless devices device "data filters," or customizable scripts, which define the data the particular customer selects to store on the mobile device. A data filter may be defined by a particular user on the user's mobile device; or, in the alternative, a menu of commonly used data filters, or "standard filters," can be generated by a system administrator or system programmer and simply selected by the user from a menu depending upon the user's particular set of circumstances and responsibilities. Standard filters may also simply be templates that an individual user can select and then customize. Both data filters and standard filters may be simple, such as an equality match, or complex, such as a multiple table join with multiple criteria.

# Please amend paragraph [041] as follows:

[041] The wireless data replicator 307 and the mobile interchange 309 provide a platform on which specialized applications can be built. In this example, the specialized applications include a mobile e-commerce application 310, a mobile hospital application 320, a mobile logistics application 330 and a mobile finance applications application 340. The particular applications 310, 320, 330 and 340 are used only as examples; in actuality, the method of the disclosed embodiment may be employed to implement any application that can benefit from mobile access to a central application or database server. The applications 310, 320, 330 and 340 are each an application component 303 of the system.

N

#### Please amend paragraph [042] as follows:

Each of the applications 310, 320, 330 and 340 includes application T0421 products 305. In this example, the application products 305 of the mobile ecommerce application 310 include [[a]] an application A1 311 (APP A1), an application A2 312 (APP A2) and an application A3 313 (APP A3). applications application products 305 of the mobile hospital application 320 include [[a]] an application B1 321 (APP B1) and an application B2 322 (APP B2). The application products 305 of the Mobile Logistics mobile logistics application 330 include an application C1 331 (APP C1), an application C2 332 (APP C2) and an application C3 333 (APP C3). Finally, the applications application products 305 of the Mobile mobile finance application 340 include an application D1 341 (APP D1), an application D2 342 (APP D2) and an application D3 343 (APP D3). Like the application components 303, the specific makeup of the application products 305 is not critical to the spirit of the invention but are used only as examples. For example, the APP A1 311 may be a mobile sales force automation (M-SFA) (MSFA) application; the APP B1 321 may be a mobile patient management system; the APP C1 331 may be a mobile delivery management system; and the APP D1 341 may be a mobile banking application.

Please amend paragraph [046] as follows:

[046] Conflicts between values may be resolved based on one of four procedures. The four procedures are "Last Write," "Timestamp Based," "Value Based," and "Timestamp and Value Based," described as follows:

(1) In the Last Write conflict resolution procedure, the last value written to the database becomes the value of an object. This method is appropriate in situations where it is highly unlikely that multiple people will want to update the same data sets. One problem with this procedure is that it is possible for a first change to over write a later change if the first change is performed off-line and not replicated until after the later change.

- (2) In the Value Based procedure, the server 107 accepts a change if the PDA's 101 'old value' matches the current value on the server.
- (3) In [[a]] the Timestamp Based procedure, if a change timestamp is greater (later) [[then]] than a current timestamp of the object on the server 107, the change is accepted. This procedure assumes that clocks on the PDA 101 and the server 107 are relatively well synchronized.
- (4) In the Value + Timestamp and Value Based procedure of conflict resolution, a change timestamp provided by the PDA 101 must be later [[then]] than the change timestamp on the server 107. Additionally, the value provided as the 'old value' by the PDA 101 must match the current value on the server 107. These conditions ensure that the change is recent, and that the user was aware of the current server's 107 representation of the object when making the change.

Note that if both the PDA 101 data repository and the server 107 data repository are capable of handling timestamps at an object attribute level (vs. the object level), then multiple request requests to updates update a particular object may be made during an update operation.

Please amend paragraph [048] as follows:

[048] The schema manager 407 maintains, for the purposes of this example, two schema, each in XML format. A first, or "main," schema describes the schema of

the server 107 and a main database[[,]] stored in a data storage 417, and the relationship among the main database's tables. Of course, as mentioned above in conjunction with Figure 1, neither the main database nor the data storage 417 have to be on the server 107, but could, for example, be on one or both of the computing devices 109 and 111 and accessed by the server 107 via the network 121. A secondary schema in the schema manager 407 describes the data organization of the PDA 101. Once data is retrieved from the main database, the schema manager 407 extracts information from the retrieved data based upon the secondary schema, and forwards the extracted information to the communication manager 403 for delivery to the PDA 101. The schema manager 407 may have additional secondary schema in order to extract information for other mobile devices such as the laptop computer 103.

### Please amend paragraph [052] as follows:

[052] Data is organized into domains in order to make the storage, collection and dissemination of the data less dependent upon the particular server process such as a DBMS any system may employ. A particular domain contains the definition of a particular object, including the individual data elements, or "attributes," that make up the object. Each attribute has a data type and one or more values. For example, an "account" object may include attributes related to a bank account such as the owner's name and the balance. On a server, an object is also the logical representation of related pieces of data. Each object has a unique identifier, or a unique key to the corresponding object. When a particular object is updated, all the data relating to that object [[is]] are also updated. Applications such as the mobile e-commerce application 310, the mobile hospital application 320, the mobile logistic logistics application 330 and the mobile finance application 340

(Fig. 3) each have collections of domains that are specific to the particular application.

Please amend paragraph [053] as follows:

[053] For example, the mobile hospital application 320 may have a patient object and a doctor object, and the mobile commerce e-commerce application 310 may include product objects. The objects for a particular application 310, 320, 330 or 340 are maintained in domain managers such as a domain manager 1 421, [[an]] a domain manager 2 422 and a domain manager 3 423. Since different types of objects typically require different [[type]] types of manipulation, each domain manager 421-423 includes a set of customized functions, or business logic, such as business logic 431, business logic 432 and business logic [[323]] 433 respectively. The domain managers 421-423 retrieve information related to their respective objects from the data storage 417 via the data access manager 415. Each domain manager 421-423 is a control point for the management of information within a corresponding domain. Procedures such as searches, adds, updates and delete operations are processed through the domain managers 421-423. The business logic 431-433 are customized domain by domain to enable processing that is unique to each particular domain. The business logic 431-433 may also include logic for resolving data conflicts.

Please amend paragraph [056] as follows:

[056] Control then proceeds to a Data Created or Updated step 507 where the process 500 determines whether the transaction represents new data or an update to existing data. An example of new data may be an account object created when the

FEB-03-2005 21:01 FOXCONN 408 919 8353 P.13

[[sale]] sales person enters information relating to a new customer. Although perhaps unlikely, if the data created or received does not change or create the local database or if the data is marked "not saved" (explained below), control proceeds from step 507 to an [[END]] End step 523 where processing for this transaction is complete. If the data is new or updated, control proceeds to a Currently Connected step 509 where the process 500 determines whether or not there is a currently active connection between the PDA 101 and the server 107. If not, control proceeds to an Insert In Sync Queue step 511 where that data is placed in [[a]] an area of memory of the PDA 101 in which pending transactions are stored. In addition, the status of the data is designated as "stale," which is explained in more detail below. If the processes process 500 determines in step 509 that the PDA 101 and the server 107 are currently connected, [[the]] control proceeds to a Synchronization step 513.

## Please amend paragraph [057] as follows:

[057] Both the insertion of data into a synchronization queue represented by step 509 and the synchronization of the data represented by step 513[[,]] involve formatting the data into a form suitable for transmission, such as by generating the contents (method names and parameters) of appropriate remote procedure calls and forming an XML message based upon the generated contents and the data created or received in step 503. In order to implement a correct and efficient synchronization, the process 500 assigns one of the following data states to each object:

(1) New: This state designates an object that has been created on the PDA 101 but does not yet exist on the server 107. An "add" object operation, or "method," pertaining to the corresponding object must be transmitted to the server 107 during the next synchronization. Some attributes of the new object such as a

unique object key need to be generated by the server 107 and then transmitted back to the PDA 101 with a confirmation that the add operation at the server 107 was successful. Of course, if the add operation is unsuccessful, the server 107 needs to transmit to the PDA 101 this fact so that appropriate action can be taken by the PDA 101.

- (2) Updated: An object designated "updated" [[have]] has been changed in the local, PDA 101 data repository since the last synchronization. Any new values of the object must be transmitted to the server 107 during a synchronization. Any conflict that occurs such as when two sales persons attempt, unknown to each other, to sell the same item is resolved at the server 107 by the replication manager 405 (Fig. 4). The updated object is then retransmitted to the PDA 101 to ensure that the copy on the PDA 101 is the same as the one on the server 107. If the replication manager 405 determines that the object from the PDA 101 is invalid due to a data conflict, then the updated object transmitted to the PDA 101 must indicate that fact.
- (3) Not saved: Objects designated "not saved" have been received from the server 107 and stored on the PDA 101. However, the object may be discarded by the PDA 101 if necessary. An example of this may be a data item with attributes that are not expected to change and the PDA 101 needs temporarily. The PDA 101 can change the state of an object from "not saved" to "saved" if the circumstances change.
- (4) Saved: An object designated "saved" is considered a permanent part of both local and remote data repositories and should match at least one defined data filter involved in the synchronization process so that its attributes are maintained in a synchronized state.
- (5) Stale: An object designated "stale" is maintained in the PDA 101 but is no longer involved in synchronization. The PDA 101 can either keep or purge

FEB-03-2005 21:01 FOXCONN 408 919 8353 P.15

objects designated stale, depending upon the requirements of the PDA 101 and/or the characteristics of the object itself.

(6) Deleted: An object designated "deleted" has been removed from the data repository of the PDA 101 and this information needs to be transmitted to the server 107 during a synchronization. A client can remove a deleted object from the local data repository and merely transmit the object's unique key to the server during synchronization or, in the alternative, mark the object for deletion and only remove it from the local data repository once a deletion of the object is successful on the server 107, as indicated during a synchronization.

Please amend paragraph [059] as follows:

[059] The decision in step 509 to proceed to either step 511 or 513 depends upon whether the PDA 101 is in an on-line mode or an off-line mode. If the PDA 101 is in [[an]] the on-line mode, then control can proceed immediately to step 513 and the XML message created in step 509 is transmitted to the server 107. However, if the PDA 101 is in [[an]] the off-line mode, the process 500 proceeds to [[the]] step 511 where the XML message is inserted in a synchronization queue and then proceeds back to [[the]] step 509 where the PDA 101 waits until a connection to the server 107 is established. The PDA 101 periodically checks to see either whether a connection has been established, such as when connection periods are regularly scheduled events or when data transfers are initiated by the server 107, or whether the conditions exist for a connection to be made, in the case of a PDA 101 that is configured to initiate a connection when the PDA 101 has one or more messages to transmit. If a new transaction is initiated while the PDA 101 is waiting for a connection to the server 107, the process 500 processes the new transaction like the previous transaction, placing the new transaction into the

synchronization queue and waiting for a connection so that a synchronization can occur with respect to all the transaction transactions in the synchronization queue.

## Please amend paragraph [060] as follows:

[060] As mentioned above, the period between synchronization synchronizations can be fixed or variable. A synchronization schedule can be established using a [[User]] <u>user</u> interface ("UI") on either the PDA 101 or the server 107. The same UI can be employed by a user either on the PDA 101 or the server 107 to initiate a synchronization. If no connection between the PDA 101 and the server 107 is available at the time a synchronization is initiated, the device 101 or 107 that initiated the synchronization recognizes this condition and leaves the request in a synchronization queue and then periodically tests for either the existence of a connection or the conditions necessary to establish a connection. Once a connection is established, synchronization proceeds and control proceeds to step 513.

# Please amend paragraph [063] as follows:

[063] There are [[five]] six synchronization actions, or operations[[,]]: a syncFilter operation, a getDeletes operation, a getCreates operation, a sendChanges operation, a sendCreates operation and a sendDeletes operation. The [[five]] six operations are described in more detail below in conjunction with Figure 6. Each operation takes two parameters, a syncRequest object and a second field, or "result flag," that indicates what information the PDA 101 wants returned from the server 107 in response to the syncRequest object. The result flag is set to one of the following values:

- (1) All: A result flag of "All" means that the server 107 should return the status and object for all object IDs associated with the operation. The "All" value should be used judiciously because it will drastically increase the amount of communication necessary between the PDA 101 and the server 107.
- (2) Updates: A result flag of "Updates" means the server 107 should return the IDs and status statuses of all objects associated with the operation. In addition, a copy of the object should be returned when the copy on the server 107 may be different than the copy on the PDA 101.
- (3) IDs: A result flag of "IDs" means the server 107 should return the object IDs and status statuses of all objects operated on during the operation. Additional messages may be returned based upon the operation type.
  - (4) Failures: A result flag of "Failures" means the server 107 return returns only error messages for objects that could not be processed during the operation.
- (5) Silent: A result flag of "silent" "Silent" means the PDA 101 is not interested in receiving any information on the operation and the server 107 should process the entire request, sending to the PDA 101 only the information that the operation is complete.

The result flags as they relate to specific operations is discussed in more detail in conjunction with Figure 6. The syncRequest timestamp denotes the last time the particular synchronization operation was executed. If a data filter is specified, the server 107 uses the data filter to limit the scope of the return set of data, or the "syncResult object."

Please amend paragraph [067] as follows:

FEB-03-2005 21:02 FOXCONN 408 919 8353 P.18

[067] The status field of a syncObject in the syncResult object represents the object's relation to the corresponding operation and is filled with one of the following codes:

- (1) Updated: A status of "updated" "Updated" means the copy on the server 107 is different than the copy on the PDA 101. This status may mean that another client has updated the data object in the database prior to the time the server 107 received the syncRequest and the PDA 101 [[need]] needs to determine an appropriate action to resolve the conflict.
- (2) Succeeded: A status of "succeeded" "Succeeded" means the syncObject was successfully processed on the server 107 and no changes were made to the syncObject while the server 107 fulfilled the request.
- (3) Failed: A status of "failed" "Failed" means the server 107 was unable to perform the request requested operation on the particular syncObject. In this case, the message filed field contains a text message as to the nature of the failure.
- (4) Same: A status of "same" "Same" means that the corresponding object on the server 107 has not changed since the timestamp on the syncObject.
- (5) New Match: A status of "new match" "New Match" means the object described by the corresponding syncObject is new to the server 107 or to the particular request since the last time the PDA 101 made the request.
- (6) Not Matched: A status of not matched "Not Matched" means the server 107 could not find the corresponding object, perhaps because it has been deleted or changed sufficiently to the extent that it no longer matches the data filter provided with the SyncRequest syncRequest object.

The status field and its meaning with respect to specific operations is discussed in more detail below in conjunction with Figure 6.

Please amend paragraph [068] as follows:

FEB-03-2005 21:03 FOXCONN 408 919 8353 P.19

[068] Once the Synchronization step 513 is complete, the process 500 proceeds to a Good Status Received step 517 where information concerning objects involved in the synchronization step 513 is checked by analyzing a return message from the server 107. If the return, or status, message indicates that a particular data update or creation was correctly performed, then control proceeds to a Mark Data Current step 519 where the value of the object in the local data repository is confirmed as matching the value of the object in the server 107 data storage 417. If the return message for a particular item indicates that an update or creation operation was not carried out on the server 107, then control proceeds from step 517 to a Rollback Transaction step 521 where the corresponding object is also set as equal to the value of the object in the server 107 data storage 417. In addition, any action taken on the PDA 101 that depended upon the creation or update of the data object must be examined to determine what further action is necessary.

## Please amend paragraph [069] as follows:

[069] Following completion of both step 519 and 523, the process 500 proceeds to the End step 523 where the process 500 is complete. It should be noted that [[the]] steps 517, 519 and 521 are iterative in nature. In other words, if a synchronization involves multiple objects such as when objects are processed [[form]] from the synchronization queue, return messages corresponding to each object must be processed through the steps 517, 519 and 521 prior to control proceeding to the End step 523.

Please amend paragraph [0070] as follows:

[070] Figure 6 is a flowchart of an exemplary synchronization process 600 corresponding to the Synchronize step 513 (Fig. 5). The process 600 begins in a Start step 601, which is initiated when the SyncRequest syncRequest operation is initiated as described above in conjunction with Figure 5. Each of the following steps represents an operation sent in conjunction with a syncRequest object. From step 601, control proceeds immediately to a Get Deletes step 603 which is associated with a GetDeletes getDeletes operation. The GetDeletes getDeletes operation retrieves all objects that have been deleted from the server 107 since the last time the GetDeletes getDeletes operation was executed.

#### Please amend paragraph [071] as follows:

[071] The GetDeletes getDeletes operation sends a time stamp timestamp and an optional list of object IDs to the server 107 in the corresponding SyncRequest syncRequest object. Typically, there is no data filter associated with this operation. However, a data filter can be sent if a particular server 107 executes a two-step delete/destroy process. The GetDeletes getDeletes timestamp should be set to the last time the PDA 101 sent a getDeletes operation (corresponding to a given data filter if a data filter is sent). If the optional list of IDs is sent to the server 107 with the getDeletes operation, then the server 107 responds to the PDA 101 by transmitting a syncResult object, described above in conjunction with Figure 5, that contains the status statuses of objects, both deleted or not deleted, with IDs on the list. If a data filter has been sent, then only the status statuses of objects matching the filter are sent. Otherwise, the server 107 responds by sending a syncResult object that contains a list of IDs of all objects that have been deleted since the last synchronization. The timestamp of the syncResult object is saved by the PDA 101 and used as the timestamp of the next syncRequest object. The PDA

FEB-03-2005 21:03 F0XCONN 408 919 8353 P.21

101 compares the list of returned IDs with its stored objects and makes appropriate changes to the local database.

Please amend paragraph [072] as follows:

[072] If the result flag of the syncRequest object is set to "All," then the server 107 returns the IDs of all objects deleted since the last getDeletes operation. If a list of IDs was provided, the syncResult will also contain the status of each ID on the list. A status of "Not Matched" indicates that the corresponding object no longer existed exists on the server 107. A status of "Updated" indicates that the corresponding object exists on the server 107 and has been updated since the timestamp on the getDeletes operation. In this case, a copy of the "Updated" object is also returned to the PDA 101.

Please amend paragraph [078] as follows:

[078] Once the server 107 receives the syncRequest object from the PDA 101, the server 107 generate generates the corresponding syncResults object, which includes a base object, which may not be the same as the new object sent by the PDA 101, showing the new object as recreated in the server's 107 database. If the result flag of the syncRequest object is set to "All," the syncResult object contains all objects and sub-objects involved in the sendCreate operation. This includes the base object showing the added object after the operation, added objects that were updated during the sendCreate process, and failure results for objects that could not be added. The "All" result flag setting is the only setting in which both the object and a status of "Succeeded" is returned. A status of Succeess "Succeeded" means that the object was added to the server 107 database without

any changes. If the result flag is set to "Updates," an ID and a status of Success, "Succeeded." but no object, is returned. If the status of the added object is "Updated," then the ID, the status and a copy of the object are returned. Typically, this situation implies that there were fields, not present in the original request, that needed to be set by the server 107. In this case, the object ID, set by the server 107, is returned in the message field. If the add fails, for any particular object, a status of Failure, "Failed." an error message in the message field and the original object are returned to the PDA101 PDA 101.

## Please amend paragraph [079] as follows:

[079] If the syncRequest [[set]] sets the result flag to the value "IDs," the syncResults object includes only the server-created IDs and the status statuses of all objects sent -- no objects are returned to the PDA 101. If the result flag is set to the value "Failures," then the syncResults object contains only the temporary ID, the status and a message relating to the reason for the failure. If the result flag is set to the value "Silent," then no information is returned to the PDA 101 about whether or not an operation succeeded or failed.

# Please amend paragraph [080] as follows:

[080] If the results result flag is set to the value "All" or "Update," the client should update the local data repository based upon the results as indicated by the syncResults object. If the results result flag is set to the value "Failure" [[of]] or "Silent," the PDA 101 should take steps to ensure the local information is still correct. If a syncResult object returns a status of "Failure, " "Failed," then the PDA 101 should take steps to correct the problem, perhaps by resubmit

FEB-03-2005 21:04 F0XCONN 408 919 8353 P.23

resubmitting the corresponding operations. Once the sendCreate operation is confirmed to be complete on the server 107, as evidenced by a suitable syncResults object, the original object can be deleted from the local data repository. If a newly created object matches a filter, it will be recreated at the next synchronization. This ensures that the PDA 101 has an accurate representation of the object. In some instances, the server 107 will fill in default fields, or otherwise update the new object before adding the object to the database.

Please amend paragraph [081] as follows:

[081] If the PDA 101 is unable to determine that the server 107 has completed an add operation, then the PDA 101 ean not know cannot know whether or not all adds were received and/or processed by the server 107. The next time the PDA 101 connects to the server 107, the PDA 101 should attempt to determine if the previous adds were successful. If this information can still not be determined, the PDA 101, or more precisely the mobile e-commerce application 310 which is executing the operations, should prompt the user to either re-submit resubmit the add requests, or remove the add requests from the local data repository.

Please amend paragraph [083] as follows:

[083] For each object in the local data repository that has changed, the PDA 101 creates a syncBase object. [[This]] The syncBase object contains the timestamp of the particular change(s) represented by this SyncBaseObject the syncBase object. The ID field is filled in with the unique [[id]] ID of this particular object. The PDA 101 also submits an updated base object in a base object field of the syncBaseObject syncBase object. Only values that have changed need to be

present. Old values are placed in another base object, one that contains the old attribute/value pairs, i.e., not the modified [[ones]] ones' values. The only values that need to be present are the original values for attributes listed in the changed base object. For example, if one value of the object is changed, the original value should be in the old values base object, and the new value should be in the [[based]] base object. The ID field of the SyncBaseObject syncBase object is the only guaranteed indicator of the target object for the change.

## Please amend paragraph [084] as follows:

- [084] The following describes information returned by the server 107 based on a particular result flag setting for the sendCreate operation.
- (1) If the result flag is set to the value "All," the server 107 returns the IDs of objects that were successfully updated and an error message for those objects which could not be updated. The current version of all objects after all updates have been processed will be returned to the client.
- (2) If the result flag is set to the value "Updates," the server 107 returns a status for each object in the request. Objects that were successfully updated will not be returned. For objects that were not successfully updated, the return set includes the ID of the updated object, and the status and the current version of the object as it is stored on the server 107. The PDA 101 can use the current version of the object to update its local data repository.
- (3) If the results result flag is set to the value "IDs," the server 107 returns the IDs and status statuses of all objects in the request. No objects are returned to the PDA 101.
- (4) If the results result flag is set to the value "Failures," the server 107 returns a result set that only includes IDs, status statuses, and failure messages

relating to objects that could not be updated on the server 107. The server 107 does not return the current version versions of the object objects.

(5) If the results result flag is set to the value "Silent," the server 107 returns no information to the PDA 101 about whether or not updates were successfully executed.

Please amend paragraph [086] as follows:

Data filters can be synchronized in batches or one at a time. For each data filter, the PDA 101, or more specifically the <u>mobile</u> e-commerce application 310 that executes the data filter, supplies a list of IDs that matched the data filter the last time synchronization was performed using that filter. The PDA 101 passes to the server 107 a vector of <u>SyncRequest syncRequest</u> objects. Each <u>SyncRequest syncRequest</u> objects objects. Within each syncObject, the PDA 101 fills in the object's ID, and the timestamp for that particular object.

Please amend paragraph [087] as follows:

[087] The server 107 returns a vector of SyncResult Objects syncResult objects. The return vector will have one SyncResult syncResult object per SyncRequest Object syncRequest object. Each SyncResult syncResult object will contain the executed filter, a timestamp showing when the filter was executed, and the vector of syncObjects. Each SyncObject syncObject has a field describing its presence in the result set using one of the following four states.

(1) If a syncObject is listed as "same," "Same," the object identifier was included in the request set of IDs. In other words, the PDA 101 already knows that the object matched the filter. Furthermore, the object has not been updated since the timestamp provided with that object in the syncRequest object. Therefore, the PDA 101 does not need to make any changes to the local data store. The server 107 can opt not to return this object to the PDA 101 in order to reduce network traffic based on the operation flag. If the object ID is missing from the Result result set, the PDA 101 can assume that the object still matches the filter and remains unchanged. The PDA 101 then updates the timestamp associated with the local copy of the object to the timestamp provided in the SyncResult syncResult object. After the timestamp is updated, the state of the local copy of the object should be 'Saved' "Saved" regardless of its previous state. Missing IDs are left in the list naming IDs that match this filter.

- (2) If the syncObject is listed as a "New Match," this object's ID was not provided in the set of known IDs in the syncRequest object. In other words, the object did not match the filter the last time this filter was synchronized. In this case, the entire object is returned to the PDA 101. The PDA 101 saves this object to the local data repository, update and updates the timestamp to the timestamp provided in the syncRequest object. The status of the object in the PDA's 101 data repository is then set to "Saved" and the object ID is added to the local list of IDs matching the filter.
- (3) A syncObject with a status of "Updated" means that the corresponding ID was in the previous result set, sent in the syncRequest object. However, the object has been updated since the timestamp for that object provided in the sync request. The entire object is returned to the PDA 101. The PDA 101 saves this object to the local data repository and updates the timestamp to the timestamp provided in the Sync Request Object syncRequest object. The local status of the

object in the PDA's 101 data repository is set to "Saved" and the object ID is left in the list of IDs matching the filter.

(4) A syncObject of status "Not Matched" was sent in the syncRequest as previously matching a particular filter. However, the object has since been updated or deleted, and no longer matches the corresponding search string. The PDA 101 sets the object state in the local data repository to "Stale" and the object ID is removed from the list of IDs matching the filter. If the object does not exist in the local data repository, then the object ID can be removed from the list of IDs.

### Please amend paragraph [089] as follows:

- [089] With the syncFilter request, the PDA 101 provides the result flag indicating how much information should be returned. The following lists what results the PDA 101 can expect based on this flag.
- (1) If the value of the result flag is "All," the server returns all objects that match the search string of the data filter. The object status will be filled in, and the entire object will be returned. If an ID no longer matches the filter, the object is marked "Not matched" Matched" and the ID is returned. [[IN]] In this case, no object is returned.
- (2) If the results result flag is set to the value "Updates," the server 107 returns the IDs of all objects that match the data filter. The server 107 does not return the entire object for those objects with a status of "same." "Same." Objects are returned if marked "Updated" "Updated" or "New Match." The server 107 also indicates which objects no longer match the filter by marking [[then]] them with a status of "Not Matched."
- (3) If the results result flag is set to a value of "IDs," the server 107 returns objects marked "Updated" or 'New Match." The

server 107 also indicates which objects no longer match the filter by marking [[then]] them "Not Matched." The server 107 does not return the ID or the object for any object listed as "Same."

(4) The "Failures" and "Silent" settings for the results result flag do not apply to this operation.

Please amend paragraph [090] as follows:

[090] Following completion of the Sync Filter step 613, the synchronization process 600 proceeds to an End step 615 where the synchronization procedure is completed. Although Figure 6[[,]] illustrates the process 600 as a series of discrete steps, this is not required by the claimed subject matter. For example, all the steps may be combined into a single syncRequest object and the server 107 can process the different operations as the server 107 sees fit, e.g., in the order suggested by Figure 6 or in some other order.

Please amend paragraph [091] as follows:

[091] Figure 7 is a flowchart of a data management process 700 on the server 107 that supports the PDA 101. The process 700 begins in a Start step 701 and control proceeds immediately to a Data Received step 703. Typically, [[the]] step 703 would be in conjunction with a Synchronization step 513 (Fig. 5). Control proceeds from step 703 to a New Data step 705 where the process 700 determined determines whether or not the data object received in step 703 has a designated status of "New," as explained above in conjunction with Figure 5. If the data is new, then control proceeds to [[a]] an Insert Data step 707 where a new data object is created and inserted into an appropriate place in the data storage 417 (Fig. 4) by

the data access manager 415 (Fig. 4). Control then proceeds to a Transmit Status step 715 where a return message is prepared for the PDA 101 that transmitted the data object, to inform the PDA 101 of the results of the data creation operation.

## Please amend paragraph [093] as follows:

[093] Figure 8 is a flowchart of an Update Notification process 800 that executes on the server 107 (Fig. 1). The process 800 begins in a Start step 801 and proceeds immediately to a Transaction Initiated step 803 where some operation has been performed on data in the remote data storage 417 (Fig. 4). In this example, the operation is either an update, add or delete operation and corresponds to a data filter associated with the user ID of the user of the PDA 101 (Fig. 1). Each operation/data filter pair is associated with a weight value, a threshold value and, in an alternative embodiment [[an]] a cumulative weight value. In some cases, the weight value and the threshold value may be the same. Once the transaction has been executed in step 803, control proceeds to a Retrieve Weight step 805 where the operation and the target(s) of the operation are compared to a list of data filters on the server 107. If the operation corresponds to a particular data filter, then a corresponding weight value for the operation/data filter pair is retrieved. In the cumulative weight embodiment, a cumulative weight value is also retrieved. The cumulative weight value is an accumulation of weight values from previous iterations of the process 800 with respect to the particular operation/data filter pair. Control proceeds to a Weight Exceed Threshold step 807 where the weight value is compared with the threshold value. In the cumulative weight embodiment, the cumulative weight value associated with the operation/data filter pair rather than the weight value is compared to the threshold value.

## Please amend paragraph [094] as follows:

[094] If neither the weight value nor the cumulative weight value, if there is one, exceed the threshold value, then control either proceeds to a Recalculate Weight step 815, in the cumulative weight embodiment, or to an End step [[815]] 817, in the non-cumulative weight embodiment. In the End step [[815]] 817, the processing with respect to this particular operation is complete. In the Recalculate Weight step 815, the weight value retrieved in step 805 is added to the cumulative weight, which is then stored in the data storage 417 in place of the old cumulative weight value. Control then proceeds to the End step [[815]] 817.

#### Please amend paragraph [095] as follows:

[095] In step 807, if either the weight value or the cumulative weight value, if there is one, exceeds the threshold value, then control proceeds to a Transmit Message step 809. In step 809, the PDA 101 is notified via a notification message that a synchronization to the local data storage is either required or recommended. The notification message is transmitted from the server 107 to the PDA 101 via a short messaging service (SMS) message. SMS is a pager-type service [[and]] well [[know]] known to those with skill in the art, and is only one example of a transmission medium for practicing the techniques of the disclosed subject matter. Each SMS message includes a data domain name, the name or some other identification of specific data filters that require an action, the type of action required, and whether or not the action needs to occur immediately. For example, if the SMS message is marked as "immediate," then the PDA 101 may need to establish a communication link and perform a synchronization at that moment. If the SMS message is marked as something other than "immediate," then the PDA

FEB-03-2005 21:06 F0XCONN 408 919 8353 P.31

101 may either synchronize immediately, wait for the next scheduled synchronization period, or put a message into a user calendar to inform the corresponding user of the need for a synchronization of the local data storage.

## Please amend paragraph [096] as follows:

Acknowledgement Received step 811. Step 811 is an optional step as indicated by the dotted lines. If the process 800 requires an acknowledgement of the receipt of the SMS message sent in step 807, then that acknowledgement may take the form of [[a]] an SMS message from the PDA 101 to the server 107 or may simply take the form of a synchronization request corresponding to the data filters specified in the notification message. Either way, if the acknowledgement message is not received by the process 800 on the server 107, control returns to step 809 where the notification message is resent. If an acknowledgement message is received in step 811 or not required in step 809, then control proceeds to a Clear Weight step 813 where the cumulative weight, if there is one, is reset. Control then proceeds to the End step 817 where processing is complete with respect to the transaction initiated in step 801.

# Please amend paragraph [097] as follows:

[097] Figure 9 illustrates an exemplary Home screen display 901 as it would appear on the display 203 (Fig. 2) of the PDA 101 (Figs. 1 and 2). The screen display 901 is shown as the first screen, once a user executes an application implementing the techniques of the claimed subject matter. As explained above in conjunction with Figure 3, a few possible applications include the mobile e-

FEB-03-2005 21:07 FOXCONN 408 919 8353 P.32

commerce application 310, the mobile hospital application 320, the mobile logistics application 330 and the mobile finance applications application 340. For the purposes of the description of Figures 9-12, the mobile e-commerce application 310 is used as an example.

## Please amend paragraph [098] as follows:

Across the top of the screen display 901 is a banner 903, which includes a [098] title, "Home," and the current time, "11:26a." Below the banner 903 is a message 905, "Welcome to Momenta!," which can be changed depending upon the circumstances. Below the message 905, several screen icons, a Catalog icon 907, an Orders icon 908, an Accounts icon 909 and a Synchronization icon 910, are displayed. Each screen icon 907-910 represents a particular function of the ecommerce application 310. By touching one of the icons 907-910 with the stylus 207 (Fig. 2), the user executes a corresponding function of the mobile e-commerce application 310. Specifically, [[The]] the Catalog icon 907 executes software on the PDA 101 that enables the user to review, and possible possibly modify, entries in a Products file; the Orders icon 908 executes software that enables the user to [[,]] place, and possible possibly modify, customer orders; the Accounts icon 909 executes software that enables the user to review, and possibly modify, the accounts of the user's customers; and the Synchronization icon 910 executes software that enables the user to define, redefine and change options on the user's synchronization filters. The examples that follow in conjunction with Figures 9-12 are related to the Catalogue Catalog icon 907 and the Products file, or database, that corresponds to a product catalog of the mobile e-commerce application 310.

Please amend paragraph [099] as follows:

Below the screen icons 907-910[[,]] is a Files flooter 913, which [099] includes options "Acct," "Order," "Catalog" and "Sync," corresponding to the screen icons 909, 908, 907 and 910 respectively. By touching one of these options with the stylus 207, the user can execute, through a series of menus (not shown), the same software executed by the corresponding screen icon 907-910. In addition to the options corresponding to the screen icons 907-910, the Files files footer 913 includes a "File" option. The File option is similar to the file option in many common programs such as Microsoft Word in that it displays a menu that enables the user to perform such actions as opening, closing and saving various files that represent the user's work. Also included in the [[file]] files footer 913 are several status icons, including a computer icon 915, which indicates whether or not the PDA 101 is in communication with a remote server 107 (Fig. 1), a stylus icon 917, which indicates whether or not the PDA 101 is enabled to use the stylus 207, and a page up icon 919, which enable enables the user to scroll the screen display 901 by touching the arrow with the stylus 207. The page up icon 919 is used when the screen display 901 does not fit within the display 203. Of course, the scroll page up icon 919 can change to a down symbol, instead of an up symbol as in this screen display 901, or both an up and a down symbol, depending upon the size of the <u>screen</u> display 901 and its relative position in the display 203.

## Please amend paragraph [0100] as follows:

[0100] Figure 10 is an exemplary Edit Filter screen display 1001 of the <u>mobile</u> e-commerce application 310 (Fig. 3) as it would appear on the display 203 (Fig. 2) of the PDA 101 (Figs. 1 and 2). The Edit Filter screen display 1001 appears on the display 203 after a user either selects the Synchronization icon 910 (Fig. 9) by touching the appropriate icon with the stylus 207 or activates the corresponding

action by means of a menu displayed by the Sync option of the files footer 913. Like the screen display 901 (Fig. 9), the screen display 1001 includes a banner 1003, which includes a title, "Edit Filter," and a current time, "4:54p." The screen display 1001 also includes a files footer 1013 and status icons 1015, 1017 and 1019, each of which serve a similar function as the [[file]] files footer 913 and the status icons 915, 917 and 919 (Fig. 9) respectively.

## Please amend paragraph [0101] as follows:

[0101] The screen display 1001 includes a Zoom icon 1021, which enables the user to change the size of the screen display 1001, either making it smaller so that more of it fits into the display 203 or making it larger so that it is easier to see. A Cancel icon 1023 enables a user to abort the currently running program and return to a previous screen display such as the Home display 901. Of course, the Zoom icon 1021 and the Cancel icon 1023, as well as the other icons, arrows, buttons, choice boxes and menus described in conjunction with Figures 9-12 are selected or activated by means of touching the stylus 207 to the appropriate symbol in the display 203 of the PDA 101. Although the particular type of user interface is not critical to the spirit of the invention, the stylus 207 and display screen 203 are employed throughout the following description of the figures.

# Please amend paragraph [0102] as follows:

[0102] The Edit Filter screen display 1001 also includes fields to enable the user to specify a data filter to modify or create. When a data filter name is entered in a Name field 1005, such as "All Products" in this example, the mobile e-commerce application 310 either retrieves information on a data filter entitled "All Products,"

FEB-03-2005 21:08 FOXCONN 408 919 8353 P.35

if the data filter already exists, or provides the screen display 1001 to enable the creation of a new data filter, if the All Products data filter does not already exist. A Sync field 1007 enables the user to specify whether or not the corresponding data filter is to be included in synchronization procedures of the PDA 101. In this example, the All Products data filter has not yet been included in synchronization as evidenced by the fact that the Sync field 1007 does not have a check.[[.]] A data filter may not be included in a synchronization because the database that the data filter corresponds to does not change often enough to justify the communication overhead of frequent synchronization. Another data filter, such as an Orders data filter (not shown), may need to be used for synchronization because of a pressing need to keep a user, or sales person, informed of changes in a company's inventory.

Please amend paragraph [0103] as follows:

[0103] A Last Sync field 1009 displays a date, "5/25/01," and a time, "4:38:40 PM," corresponding to a time and date when the All Products data filter was last used in a synchronization. A Query field 1011 shows an actual corresponding data filter, written using a syntax that should be easily recognizable to those with skill in the art. In this example, the data filter specifies that the All Products data filter retrieve all records in the Products database, i.e., a term "PrName" specifies a particular attribute in the Products database and an operator "==" specifies that records [[equal]] equalling the final term, or '\*', should be retrieved and displayed. Since the term '\*' is a wildcard character that matches any value, this particular data filter retrieves and displays all records in the Products database.

Please amend paragraph [0104] as follows:

[0104] A properly formed data filter, or search string, can be described using Backus Naur Form ("BNF") notation as follows:

- (1) filter = "(" filtercomp ")"
- (2) filtercomp = and | or | simpleFilter
- (3) and =  $^{\circ}$ % filterlist
- (4) or = "|" filterlist
- (5) filterlist = 1\*filter
- (6) simpleFilter = attributeName filtertype value
- (7) filtertype = "==" | ">=" | "<=" | "!="

An attributeName is alphanumeric and corresponds to a column in the Products database or file. Binary attributes are not used within a data filter, i.e., a data filter ean not cannot compare two JPEG images for equality. A value corresponds to any permissible entry for an attribute, e.g., the price of a baseball can be almost any numeric value such as \$5.00; the value of a product name is typically a noun such as "baseball."

Please amend paragraph [0105] as follows:

[0105] Figure 11 illustrates a first exemplary Find Product screen display 1101 of the mobile e-commerce application 310 as it would appear on the display 203 (Fig. 2) of the PDA 101 (Figs. 1 and 2). The Find Product screen display 1101 is an entry screen that enables the user, or sales person, to define or modify a data filter using the display 203 and the stylus 207 (Fig. 2). Like the display screen display 901 (Fig. 9) and the display screen display 1001 (Fig. 10), the display screen display 1101 includes a banner 1103, which includes the name of the display screen display 1101, "Find Product," and the current time, "11:38a"; a files footer

1113; and status icons 1115, 1117 and 1119, all of which exhibit similar functionality to the corresponding banner, files footer and status icons in Figures 9 and 10. Under the banner 1103, the display screen display 1101 includes two icons, an Execute icon 1105 and an Advanced Filter icon 1121. When the user touches the Execute icon 1105 with the stylus 207 (Fig. 2), a current data filter, corresponding to the information displayed in the display screen display 1101, is executed. In this example, the current data filter is the same as the data filter described above in conjunction with Figure 10, or "PrName == '\*'. When the user touches the Advanced icon 1121 with the stylus [[203]] 207, the current display screen display 1101 is replaced with another Find Product display screen display 1201, described below in conjunction with Figure 12. The display screen display 1201 enables the user to create or modify more complicated, or advanced, data filters.

## Please amend paragraph [0106] as follows:

[0106] The display screen display 1101 includes a Search [[Field]] field 1125, in which the user enters a particular attribute name from, in this example, the Products file. When an inverted triangle at the right edge of the search Search field 1125 is touched with the stylus 207, a drop-down pick list is displayed, enabling the user to select an attribute from the Products file, or database table, if desired. A search value Search Value field 1127 enables the user to enter a value that he wants to use in the data filter being defined or created. In this example, the value is equal to '\*", which is a wildcard character that matches any value in the file. Thus, all the records in the Products file would be returned. Another example of a value that may be entered in the search value Search Value field 1127 is "baseball," which would cause the data filter to return any entry in the Products file in which the product name is equal to the word "baseball." If the user entered the

term "base\*", then the data filter would return all the records in the Products file corresponding to "baseballs" or "baseball bats." Two operator entry fields 1107 enable the user to specify a desired relation between the search Search field 1125 and the search value Search Value field 1127. In this example, the two operator field 1107 choices, only one of which can be selected, are '=' and '!='. The '=' operator field 1107 indicates that the user wants the data filter to return all entries in the Products file in which the attribute entered in the search Search field 1125 equals the value entered in the search value Search Value field 1127. If the user selects the '!=" operator field 1107, then the user wants the data filter to display all entries in the Products file in which the attribute specified in the search Search field 1125 does not match the value entered in the search value Search Value field 1127.

Please amend paragraph [0107] as follows:

[0107] A show values Show Values check box 1109 enables the user to specify a "fuzzy" search. In other words, instead of searching for entries in which the attribute named in the search Search field 1125 exactly matches the value entered in the search value Search Value field 1127, the data filter returns all entries in the Products file in which the match is close. A Match match icon 1111 provides similar functionality to the show values Show Values check box 1109, but enable enables the user to execute the data filter and see the results immediately. A cancel Cancel button 1123[[,]] aborts the current data filter definition or creation process and returns the display 203 to a previously displayed display screen.

Please amend paragraph [0108] as follows:

Figure 12 illustrates a second exemplary Find Product screen display [0108] 1201 as it would appear on the display 203 (Fig. 2) of the PDA 101 (Figs. 1 and 2). Like the Find Product screen display 1101 (Fig. 11), the Find Product screen display 1201 is an entry screen that enables the user, or sales person, to define or modify a data filter using the display 203 and the stylus 207 (Fig. 2). However, unlike the display screen display 1101, which enables the user to enter create or modify a simple data filter, the display screen display 1201 enables the user to create or modify more advanced, or complex, data filters. Like the display screens screen displays 901 (Fig. 9), 1001 (Fig. 10), and 1101, the display screen display 1201 includes a banner 1203, which includes the name of the display screen [[1101]] display 1201, "Find Product," and the current time, "4:46p"; a files footer 1213; and status icons 1215, 1217 and 1219, all of which exhibit similar functionality to the corresponding banner, files footer and status icons in Figures 9, 10 and 11. Like the Find Product display screen display 1101, the display screen display 1201 includes a [[Match]] match icon 1211 and a Cancel button 1223, which function in [[a]] similar fashion to the [[Match]] match icon 1111 and the Cancel button 1123 (Fig. 11), respectively.

## Please amend paragraph [0109] as follows:

[0109] Under the banner 1203, the display screen display 1201 includes two icons, an Execute icon 1205 and [[an]] a Simple icon 1221. When the user touches the Execute icon 1205 with the stylus 207 (Fig. 2), a current data filter, corresponding to the information displayed in a display box 1235, or in this example "(&(PrName=\*Base\*)(PrRetailPrice>=5.00))", is executed. Simply, the current data filter returns entries in the Products database in which the word "base" is some where somewhere in the name of the product and the price is greater than or equal to \$5.00. For example, entries for baseballs, baseball mitts, baseball bats

FEB-03-2005 21:09 FOXCONN 408 919 8353 P.40

and baseball gloves that cost \$5.00 or more are all returned for display on the PDA 101. The meaning and syntax of such data filters is well known to those with skill in the art. At the right edge of the display box 1235 is an up arrow and a down arrow, which when touched by the stylus 207, cause the display box 1235 to scroll if the current data filter is too large to fit within the confines of the display box 1235. If the user touched touches the stylus 207 to the Simple icon 1221, the PDA 101 displays the Find Product display screen display 1101 on the display 203 of the PDA 101.

## Please amend paragraph [0110] as follows:

Like the Find Product display screen display 1101, the display screen display 1201 enables the user to enter a data filter, albeit a more complex one than the data filters of the screen display screen 1101. A Search [[Filed]] field 1225 enable enables the user to select multiple attributes of the Products database, one attribute at a time. A Search Value [[filed]] field 1227 enables the user to enter a price or other appropriate value to employ in a search of the database. Instead of the two Operators field choices operator entry fields provided above in the screen display screen 1101, the display screen display 1201 includes four Operators operator entry fields choices 1207, a '=' operator, or "equal to," a "!=" operator, or "not equal to," a ">=" operator, or "greater than or equal to," and a "<=" operator, or "less than or equal to." A Show Values check box 1209 functions in a similar fashion as the Show Values check box 1109 of the display screen display 1101.

Please amend paragraph [0111] as follows:

The display screen display 1201 also includes a Build button 1229, two [0111] Conjunction conjunction buttons 1231 and a Reset button 1233. The Build button 1229 moves a new search string specified by the Search field 1225, the Operators check boxes operator entry fields 1207 and the Search Value field 1227 into the expression displayed in the display box 1235. The Conjunction conjunction buttons [[1232]] 1231 determine the relationship in a compound search string between the new search string moved by the Build button 1229 and an existing search string, if there is one, already displayed in the display box 1235. An "And" conjunction button 1231 creates a compound search string in which the conditions of both the new search string and the existing search string must be satisfied for an entry in the Products database to be displayed. An "Or" conjunction button 1231 creates a compound search string in which one or both of the conditions represented by the new search string and the existing search string must be satisfied for an entry in the Products database to be displayed. The Reset button 1233, when touched by the stylus 207, clears the display box 1235, thus enabling the user to start over in the creation of a search string.

Please amend paragraph [0112] as follows:

[0112] Using the screens of Figures 9-12, the user can define data filters employed to practice the techniques of the disclosed embodiment. Figures 9-12 represent only a select portion of a graphical user interface (GUI), displayed on the display 203 of the PDA 101, that enables the execution of the mobile e-commerce application 310. The other applications 320, 330 and 340 have their own particular functionalities, GUIs and corresponding screens. While various embodiments of the invention have been described, it will be apparent to those of ordinary skill in the art that many more embodiments and implementations are

possible that are within the scope of this invention. Accordingly, the invention is not to be restricted except in light of the attached claims and their equivalents.
